

# **MADS - Deployment 2**

**It works on my machine**

**Raoul Grouls, 2 December 2024**

# Docker Fundamentals: Key Concepts

**Dockerfile** -> builds -> **Image** -> runs -> **Container**

You should have  
produced  
something like this

```
1 FROM python:3.12-slim
2 WORKDIR /app
3 RUN pip install --no-cache-dir requests loguru
4 COPY ingest/ingest.py .
5
6 CMD ["python", "ingest.py"]
```

```
1 FROM python:3.11-slim
2 WORKDIR /app
3 RUN pip install --no-cache-dir pandas loguru pyarrow
4 COPY preprocess/preprocess.py .
5
6 CMD ["python", "preprocess.py"]
```

```
1 FROM python:3.12-slim
2 COPY model/requirements.txt .
3 RUN pip install --no-cache-dir -r requirements.txt
4
5 WORKDIR /app
6 COPY model/*.py .
7 EXPOSE 8000
8
9 ENTRYPOINT ["uvicorn", "serve:app", "--host", "0.0.0.0", "--port", "8000"]
```

```
1 build:
2     docker build -t mads-ingest -f ingest/ingest.Dockerfile .
3     docker build -t mads-preprocess -f preprocess/preprocess.Dockerfile .
4     docker build -t mads-model -f model/serve.Dockerfile .
5
6 run:
7     docker run \
8         -v ./data:/app/data \
9         -v ./logs:/app/logs mads-ingest
10    docker run \
11        -v ./data:/app/data \
12        -v ./logs:/app/logs mads-preprocess
13    docker run \
14        -v ./data:/app/data \
15        -v ./logs:/app/logs \
16        -p 8000:8000 \
17        mads-model
18
19 clean:
20     rm -rf data/*
```

- You can also use docker-compose
- It makes it easier to combine multiple docker containers

```
1 services:
2   ingest:
3     build:
4       context: .
5       dockerfile: ingest/ingest.Dockerfile
6     volumes:
7       - ./data:/app/data
8       - ./logs:/app/logs
9
10    preprocess:
11      build:
12        context: .
13        dockerfile: preprocess/preprocess.Dockerfile
14      volumes:
15        - ./data:/app/data
16        - ./logs:/app/logs
17      depends_on:
18        - ingest
19
20    model:
21      build:
22        context: .
23        dockerfile: model/serve.Dockerfile
24      volumes:
25        - ./data:/app/data
26        - ./logs:/app/logs
27      ports:
28        - "8000:8000"
29      depends_on:
30        - preprocess
31
32      healthcheck:
33        test: ["CMD-SHELL", "curl -f http://localhost:8000/health && exit 0 || exit 1"]
34        interval: 10s
35        timeout: 10s
36        retries: 3
37        start_period: 10s
38      restart: unless-stopped
39
```

# Docker compose

## Services Architecture:

- Three connected services: ingest, preprocess, and model
- Pipeline flow: ingest → preprocess → model

## Common Patterns:

- Each service has dedicated Dockerfile
- Shared volumes for data and logs
- Volume mounts persist data to host machine

## Key Features:

- Model service exposes port 8000

- Health checks on model service
- Automatic restart policy
- Service dependencies ensure correct startup order

## Volume Configuration:

- ./data:/app/data - shared data directory
- ./logs:/app/logs - centralized logging

## Health Checks (model):

- 10s intervals with 3 retries
- 10s startup grace period
- Curl test to /health endpoint

# Docker compose commands

`docker compose up`

- Starts all services defined in compose file
- Shows logs in terminal
- Creates networks/volumes if needed
- Builds images if not present

`docker compose up -d`

- Starts services in detached mode
- Runs in background
- No logs in terminal
- Returns control to shell

`docker compose down`

- Stops all running containers
- Removes containers and networks
- Preserves volumes by default
- Add -v flag to remove volumes

`docker ps`

- Shows running containers
- Displays: Container ID, Image, Command, Status, Ports
- Add -a flag to show stopped containers
- Useful for checking container health

# uv-example

An example where

- curl is installed
- uv is installed to speed up installation of dependencies

```
18 # Base image
17 FROM python:3.12
16
15 # this updates dependencies, installs curl and
14 # rm -rf /var removes files only necessary during installation
13 RUN apt-get update && apt-get install -y curl && rm -rf /var/lib/apt/lists/*
12
11 WORKDIR /app
10
9 ADD --chmod=755 https://astral.sh/uv/install.sh /install.sh
8 RUN /install.sh && rm /install.sh
7
6 COPY ./requirements.txt .
5 RUN /root/.local/bin/uv pip install --system --no-cache -r requirements.txt
4
3 COPY test.py test.py
2 ENTRYPOINT ["python", "test.py"]
1
```

# Smaller torch builds

Dockerfile:

- FROM cnstark/pytorch:2.0.1-py3.10.11-ubuntu22.04

pyproject.toml:

```
[[tool.rye.sources]]  
name = "torch-cpu"  
url = "https://download.pytorch.org/whl/cpu"
```

# Makefile

- **Target:** File to be created or action to perform
- **Prerequisites:** Files or targets needed before recipes can run
- **Recipe:** Commands (indented with TAB) that make runs to create target or perform action
- `.PHONY` tells make these targets don't create actual files

```
target: prerequisites  
    recipe  
    recipe  
    ...
```

# Makefile

- Checks if target (\$@) is missing or older than source (\$<)
- Creates directory and copies only if needed
- Automatic variables:
  - \$< (first prerequisite),
  - \$@ (target name)

Chain of dependencies:

- Run depends on clean and build
- Build depends on img/clustering.png
- Make resolves these automatically in correct order

```
29 img/clustering.png: .. /img/clustering.png
30 |     mkdir -p img
31 |     cp $< $@
32 |
33 build: img/clustering.png
34 |     @echo "${YELLOW}Building Docker image ... $(NC)"
35 |     docker build -t $(IMAGE_NAME):$(IMAGE_TAG) .
36 |     @echo "${GREEN}Build complete!$(NC)"
37
```

```
35 run: clean build
36 |     @echo "${YELLOW}Starting container ... $(NC)"
37 |     docker run -d -p $(PORT):$(PORT) --name $(IMAGE_NAME) $(IMAGE_NAME):$(IMAGE_TAG)
38 |     @echo "${GREEN}Service running on http://localhost:$(PORT)$(NC)"
39 |     @echo "${GREEN}View image on on http://localhost:$(PORT)/show$(NC)"
40
```

# Straattaal

- artefacts: contains data we create
- assets: data we obtained
- src/slanggen: python src code for scraping, preprocessing and training a PyTorch model
- backend: python code that uses the trained model for inference
  - Includes static folder with css/html

```

# Straattaal

`dist/` is the distribution directory containing packaged versions

`slanggen-0.4-py3-none-any.whl`

- Wheel format (.whl) - faster to install than source distributions
- py3: Python 3 compatible
- any: Works on any platform

`slanggen-0.4.tar.gz`

- Source distribution (sdist)
- Contains raw source code and build instructions
- Fallback if wheel installation fails
- Required for PyPI distribution

Both files represent version 0.4 of the slanggen package, just in different formats.

# Installing dist

```
RUN --mount=source=dist,target=/dist PYTHONDONTWRITEBYTECODE=1 pip install --no-cache-dir /dist/*.whl
```

- RUN: Dockerfile instruction that executes commands during image build
- `--mount=source=dist,target=/dist`: Temporarily mounts local `dist` directory to `/dist` in container during build
- `PYTHONDONTWRITEBYTECODE=1`: Prevents Python from creating `.pyc` files
  - Container images should be immutable - `.pyc` files create varying builds
  - Adds unnecessary size to container images
  - Can cause permission issues in some container setups
- `pip install --no-cache-dir /dist/*.whl`: Installs all wheel files from mounted `/dist` directory without caching
